Title

The Role of Tilt in Face Gaze Behavior

INTRODUCTION

The **left-gaze bias (LGB)** is a tendency to fixate the left side of the face (from the observer's perspective).

Campbell (1978);
Guo et al., (2009);
(and many others)

Previous research only examined the LGB in upright or inverted faces.

Q: What happens when faces are *tilted*?

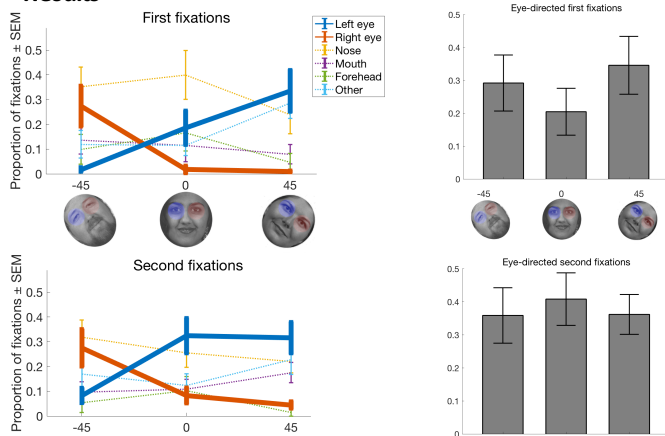

We hypothesized that the **salience of the upper eye** in tilted faces would compete with the LGB, and lead to an **upper eye bias**.

EXPERIMENT 1

- Participants (n=15) completed an expression recognition task with faces appearing at: -45° 0° or $+45^\circ$
- Eye movements were tracked at 60Hz with a GazePoint tracker.
- Independent coders marked the locations of the first two fixations.

Results

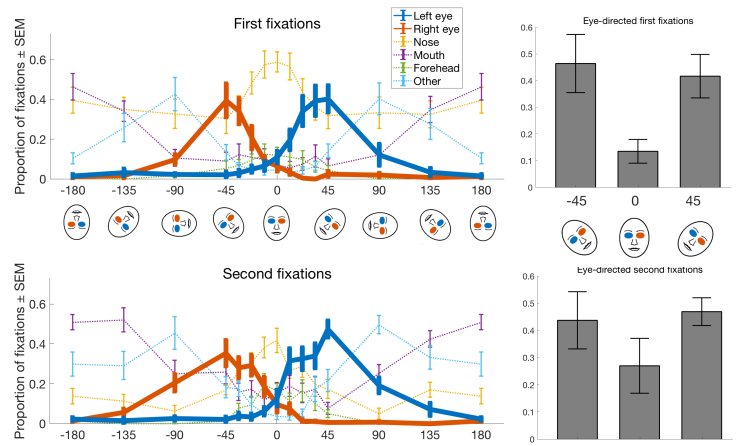

Davidenko, Kopalle, & Bridgeman (Perception, 2019)

EXPERIMENT 2

- Participants (n=13) completed a similar task with faces appearing at: $\pm 180^\circ$ $\pm 135^\circ$ $\pm 90^\circ$ $\pm 45^\circ$ $\pm 33.75^\circ$ $\pm 22.5^\circ$ $\pm 11.25^\circ$ or 0°
- Same eye tracking and coding as in Exp. 1

Results

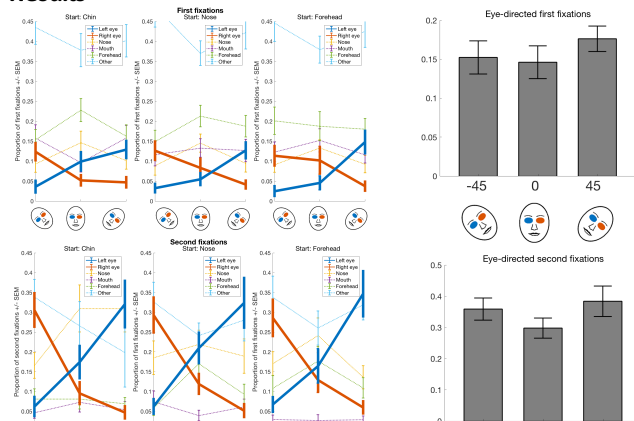

Davidenko, Kopalle, & Bridgeman (Perception, 2019)

EXPERIMENT 3

- Participants (n=20) completed an expression recognition task similar to Exp. 2, with faces appearing at: -45° 0° or $+45^\circ$
- Vertical position of face varied randomly**, such that the initial fixation was on the chin, nose, or forehead.

Results

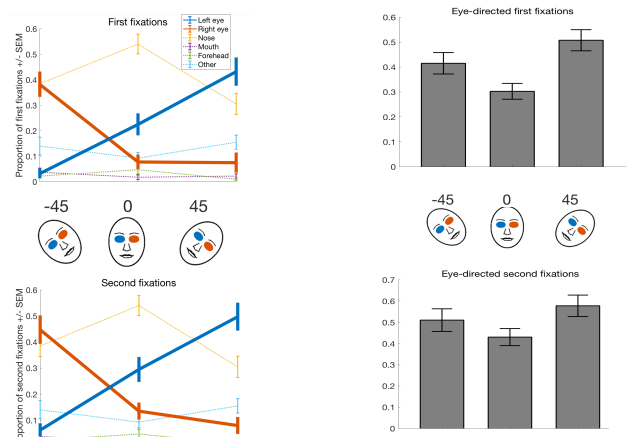

Davidenko, Sweeney, Cardilla, & Akhtar (in preparation)

EXPERIMENT 4

- Participants (same n=20 as in Exp. 3) completed an expression rating task with **short videos** (~1 second) of faces making dynamic expressions at: -45° 0° or $+45^\circ$

Results

Davidenko, Sweeney, Cardilla, & Akhtar (in preparation)

CONCLUSIONS

Tilted faces elicit a **robust upper eye bias** that dominates the LGB at 45 degrees.

Tilted faces elicit **more eye-directed fixations** than upright faces, but **no change in behavior**.

Fixating the upper eye of tilted faces may be **optimal** for cortical processing (de Haas et al., 2016).
